Progress Presentation

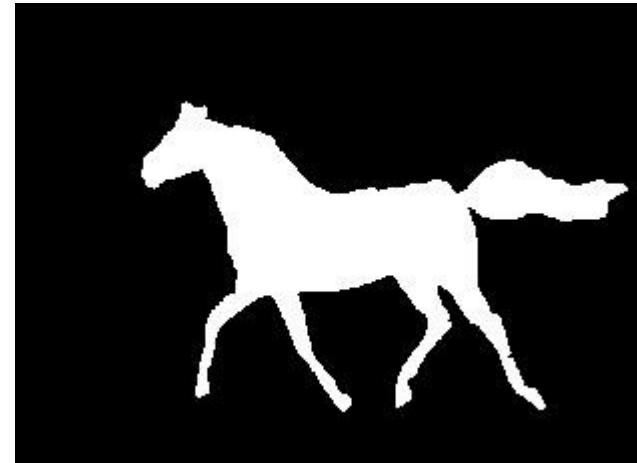

Combined Top-Down/Bottom-Up
Segmentation

Firat Kalaycilar
firat@lems.brown.edu

Based on PAMI'08 Paper by Borenstein and Ullman

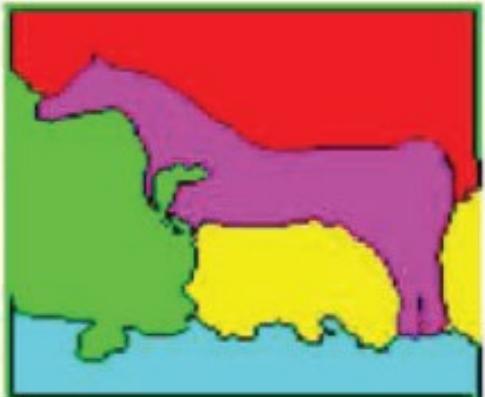

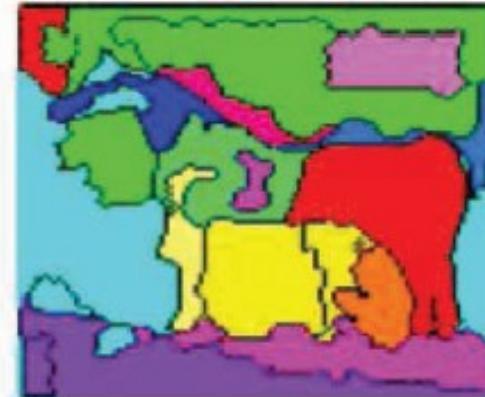

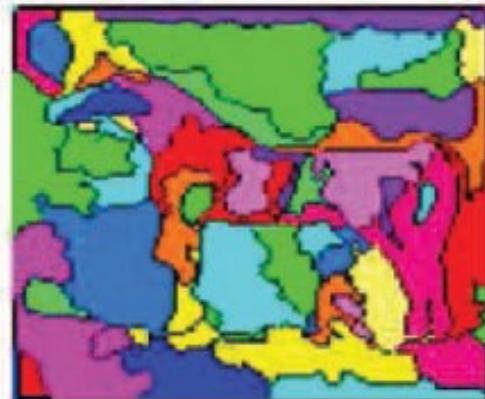

Problem

- Figure-ground image segmentation
 - The task of finding two sets of pixels:
 - A set of figure (object) pixels
 - A set of ground (background) pixels

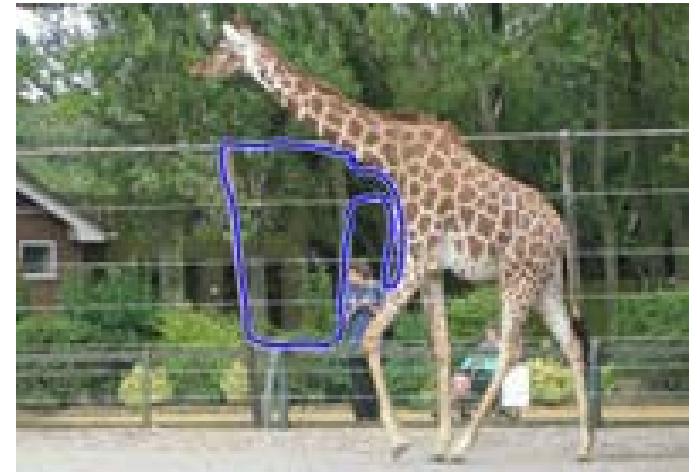

Bottom-Up Segmentation

- Segmentation as a bottom-up process
 - No stored object representation.
 - Segment image into homogenous regions using some image based criteria.
- Advantage: Informative about the exact object boundaries
- Disadvantage: Over/Undersegmentation

Top-Down Segmentation

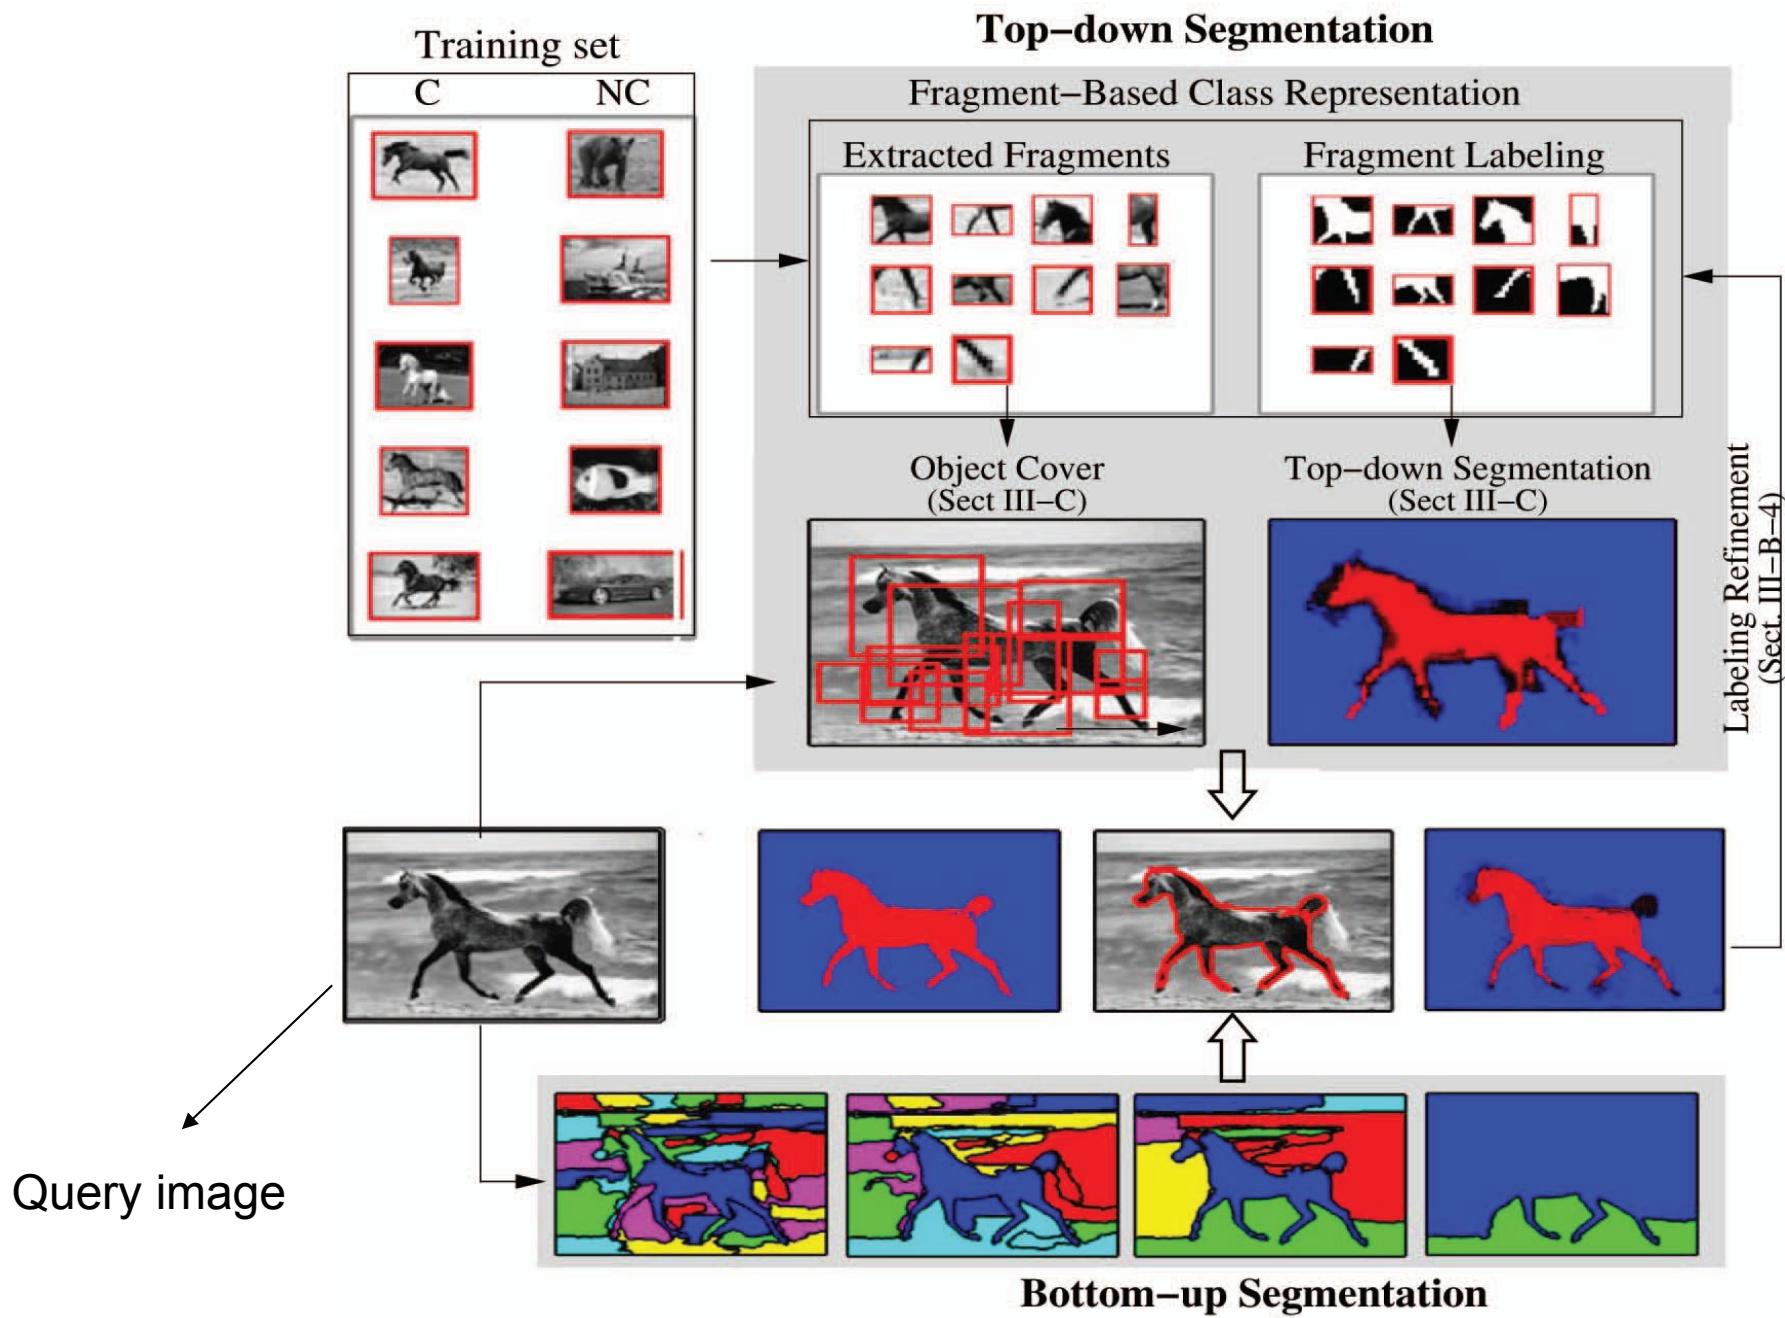

- Segmentation as a top-down process
 - Stored object representations.
 - Look for the object using prior knowledge about its possible appearance and shape.
- Advantage: We know what we are looking for.
- Disadvantage: Object representation cannot model the entire class perfectly.

Combined TD/BU Segmentation

- Idea is to make use of the advantages of both approaches.
 - TDS can produce a preliminary segmentation.
 - BUS can refine it to obtain a better delineation of the object boundary.

Combine TDS and BUS

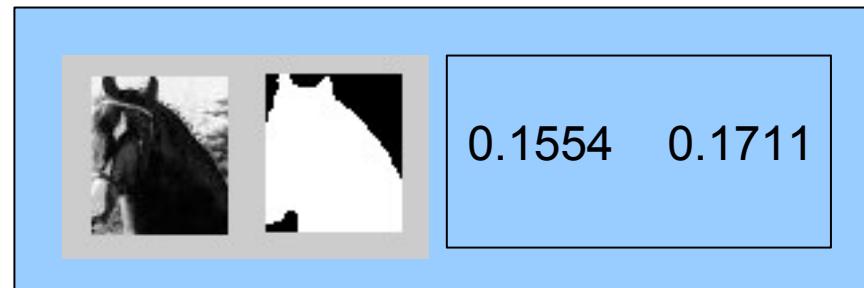

Components

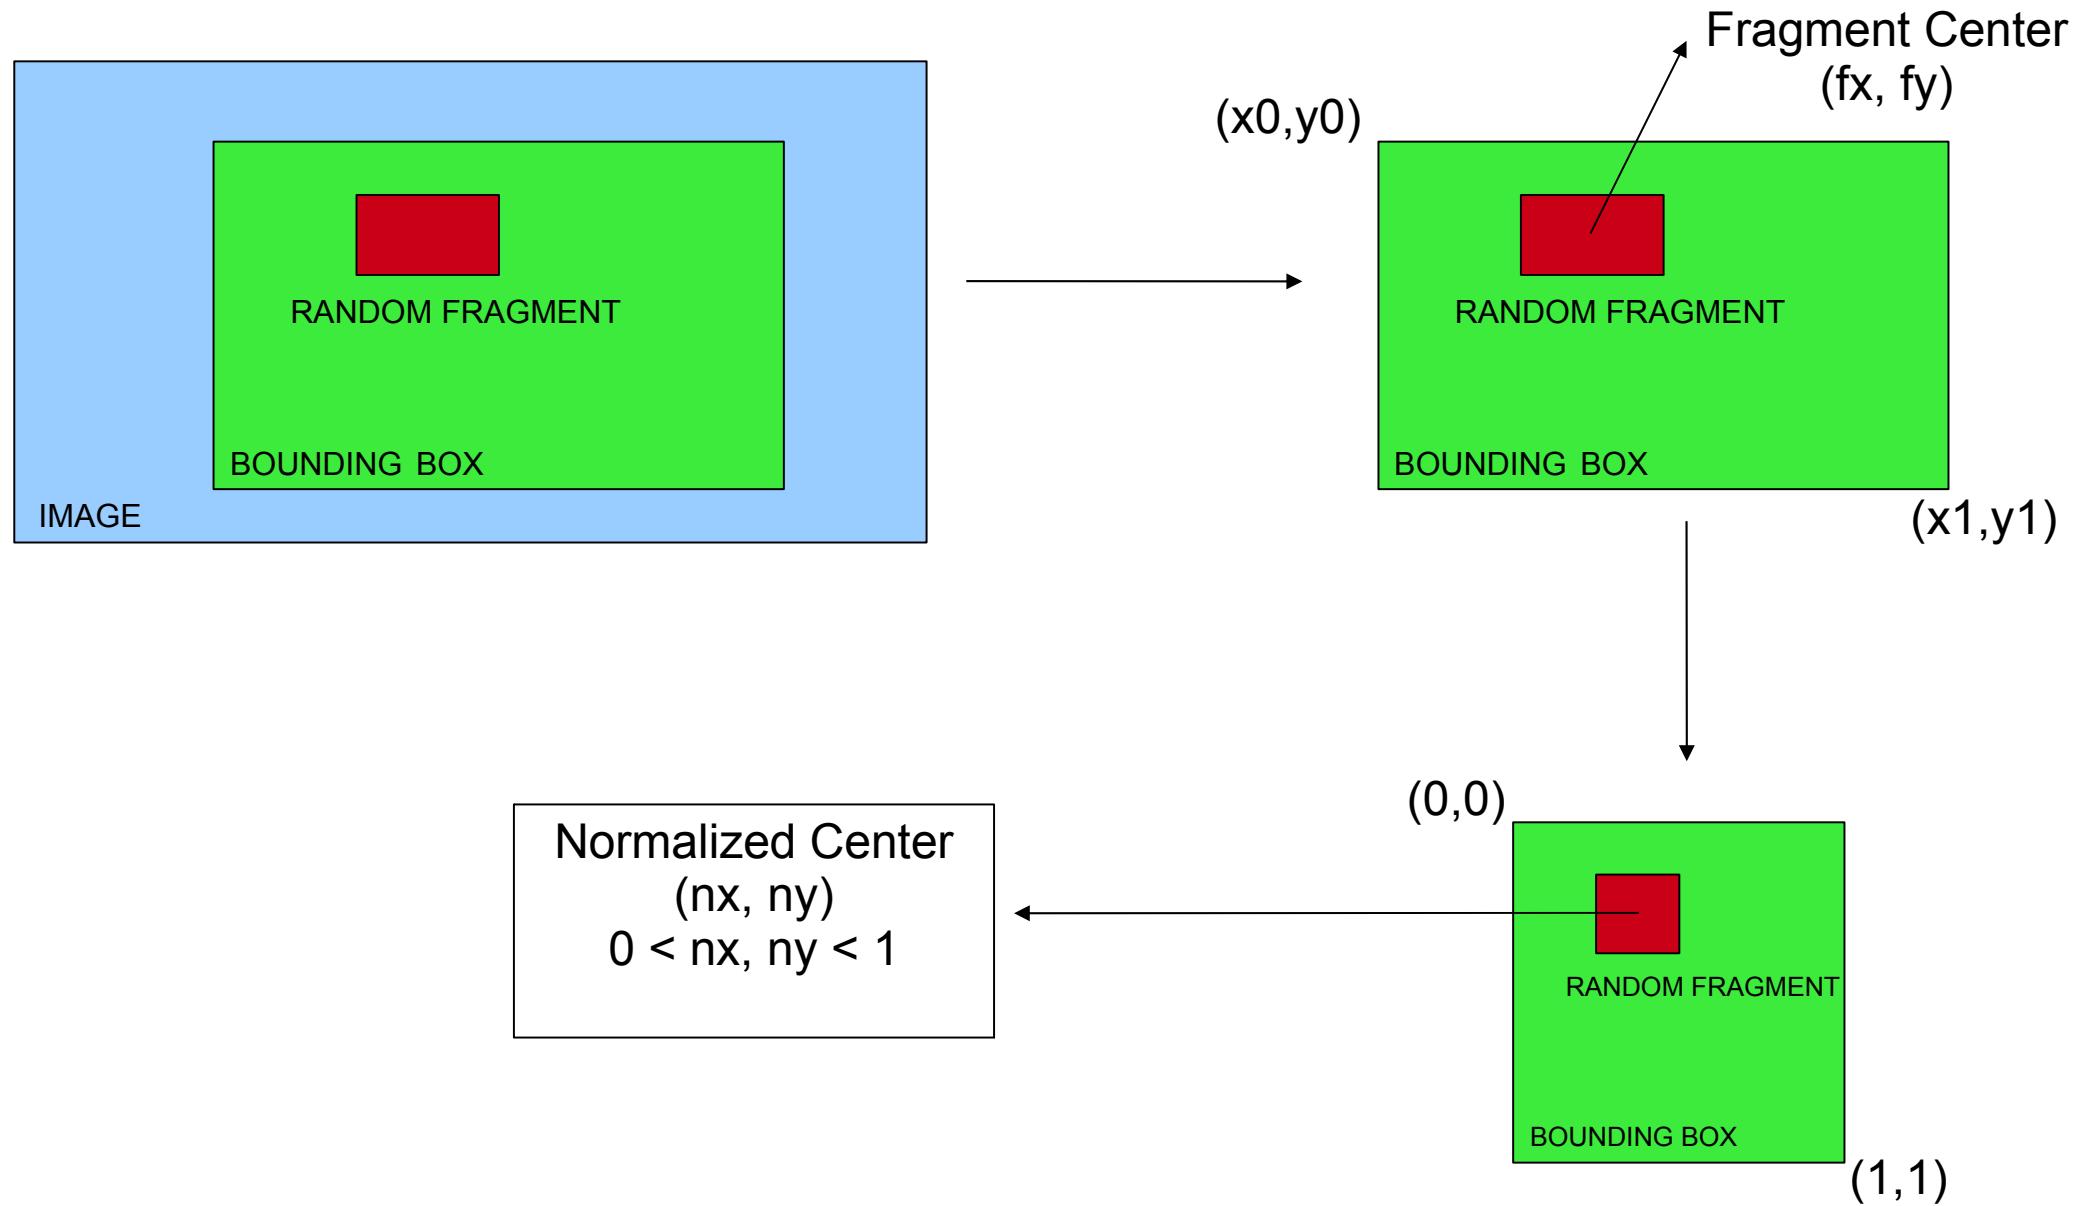

- Fragment Bank Construction (Training)
- Bottom-up segmentation (BUS)
- Top-down segmentation (TDS)
- Combining BUS and TDS (CSEG)

Fragment Bank Construction

- Divide the dataset into two parts: Training and Test sets
- In this stage, only use the training images.
- For each training image
 - Randomly extract N rectangular patches
 - Extract N corresponding groundtruth patches using the groundtruth figure-ground segmentations of the training images.
 - For every fragment, compute and record its normalized center.

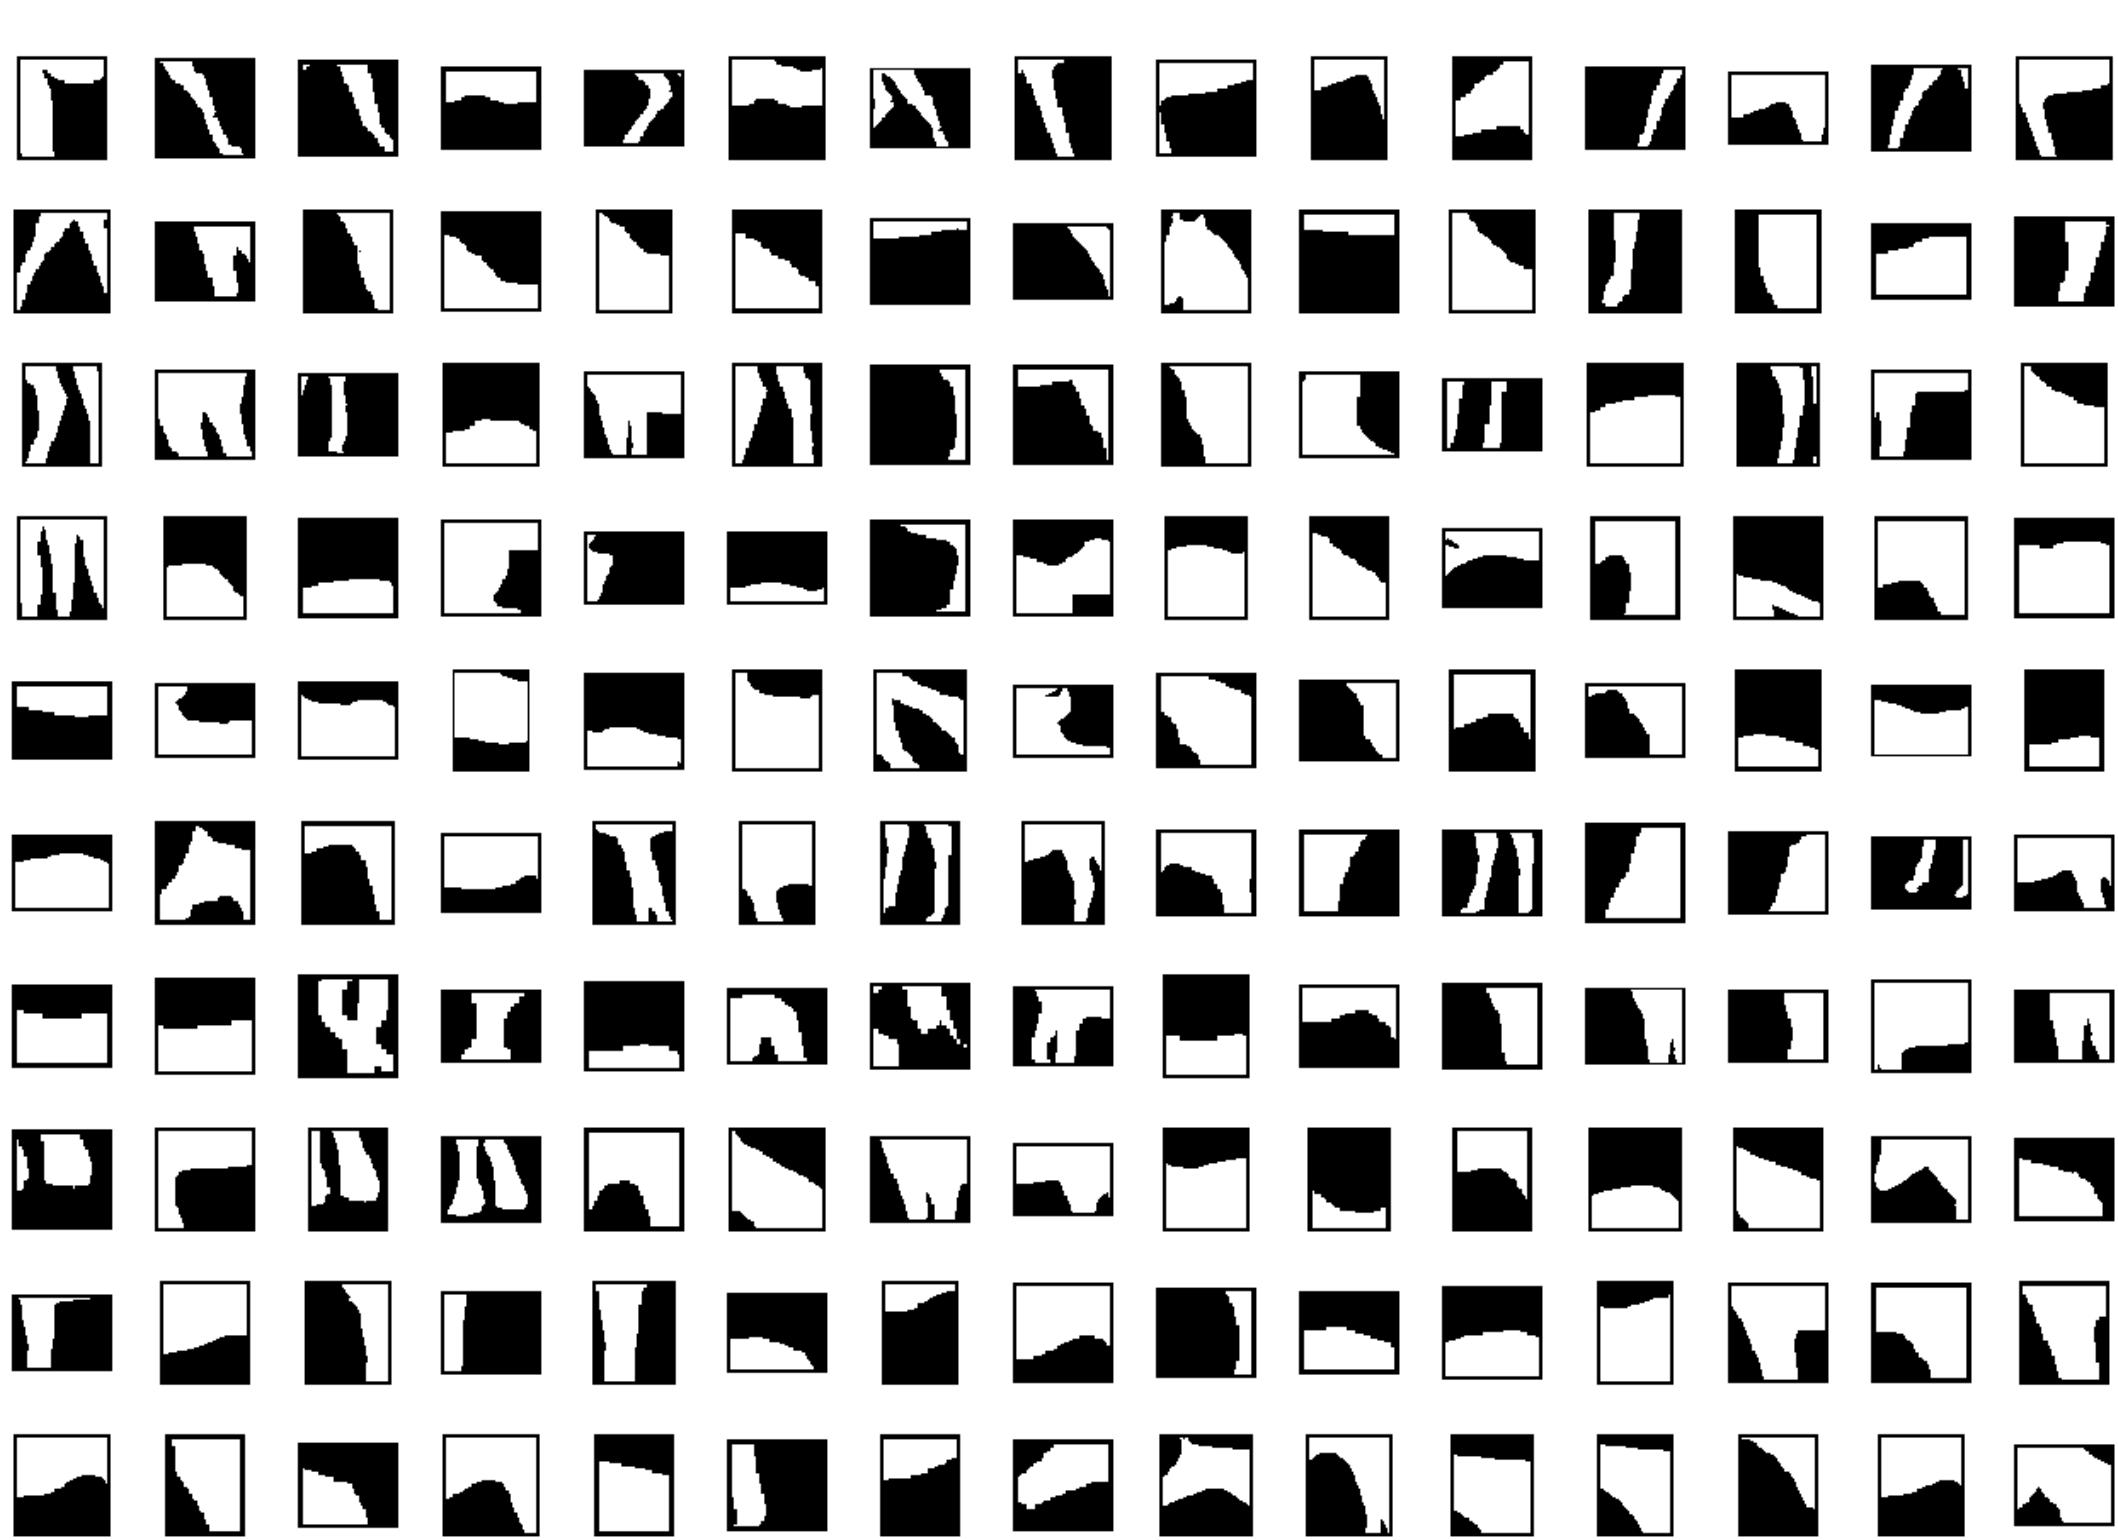

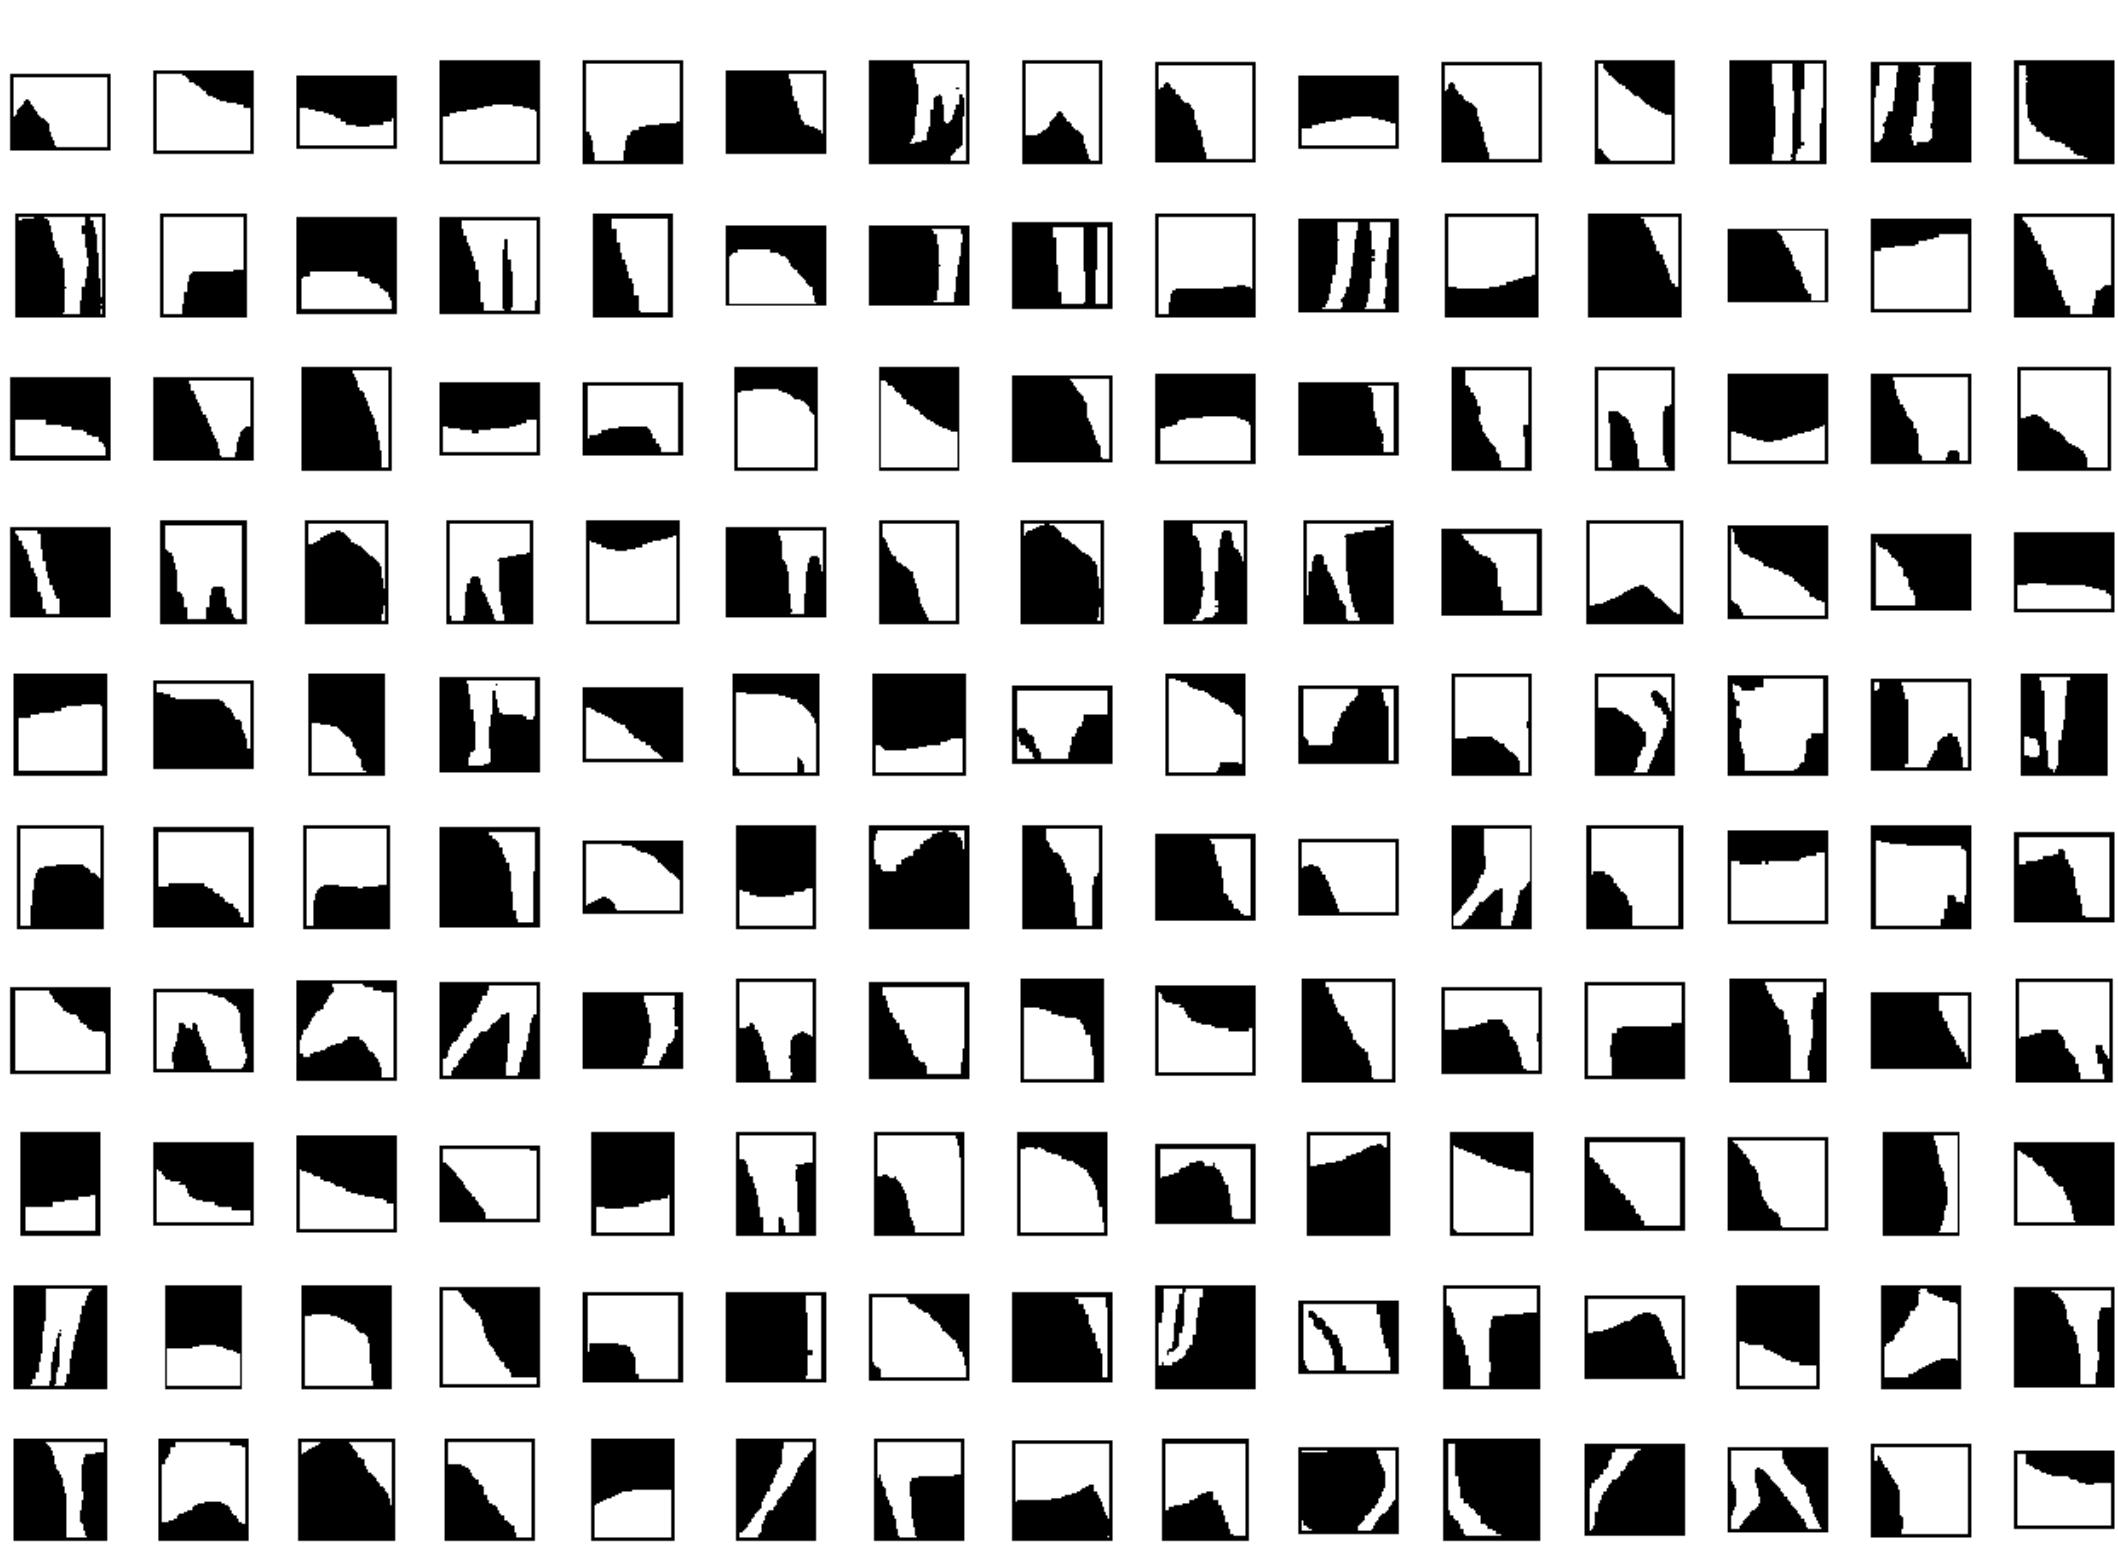

Normalized Center

Fragment Bank Construction

- Make sure that each gray level patch and its corresponding groundtruth figure-ground segmentation satisfies the following criteria:
 - $0.7 \leq \text{Aspect ratio} \leq 1.43$
 - $0.15 \leq \text{Relative area of the figure (white)} \leq 0.85$
 - $1000 \leq \text{Width} \times \text{Height} \leq 3000$
- We can reduce the number of fragments by eliminating them randomly
 - For example; first I extracted 600 (20 frags/horse x 30 horses) fragments. Then I reduced the fragment bank size to 300.

Bottom-up Segmentation

- “Efficient Graph Based Image Segmentation”
by Felzenszwalb and Huttenlocher, IJCV 2004
 - Very fast
 - Has only 3 parameters
 - A hierarchical segmentation can be obtained by just varying the parameters.
- Currently, I use flat segmentation.

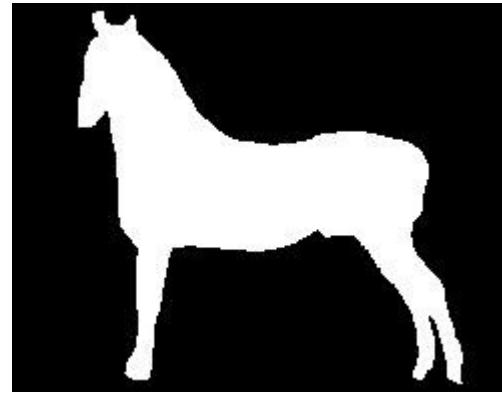

Top-down Segmentation

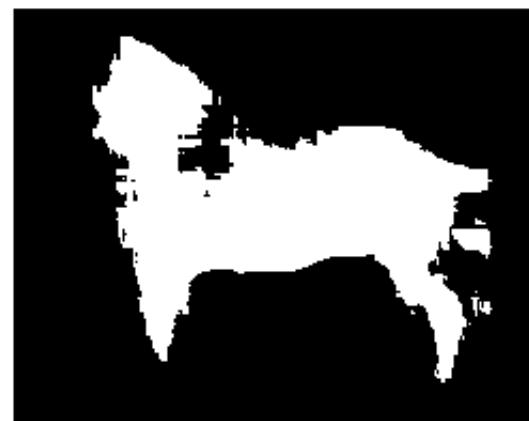

- In this stage, only the test images are used.
- For each test image
 - For each fragment of the fragment bank
 - Compute normalized cross correlation.
 - Use non-maximum suppression to find the locations of high responses.
 - Keep the locations having responses (R) greater than a threshold.
 - Skip if there is no location left. Else continue.
 - Normalize each location.
 - Compute the squared distance (D) between the stored normalized center and the normalized location. $(1 - D/2)$ is the spatial consistency score (SC).
 - Compute the final score as
 - $FS = \alpha \times R + (1 - \alpha) \times SC$
 - $0 \leq \alpha \leq 1$.
 - Transfer the groundtruth figure-ground labeling of the fragment to the location yielding the highest FS.
 - Select the pixels covered by sufficient amount of fragments as foreground.

TDS output

Combining TDS and BUS

- For each test image
 - For each BU segment of the image
 - Compute the ratio of the pixels detected as foreground at the end of TDS.
 - If the ratio is greater than a threshold, label the entire BU segment as foreground.
 - Otherwise, label the entire BU segment as background.

Experimental Results

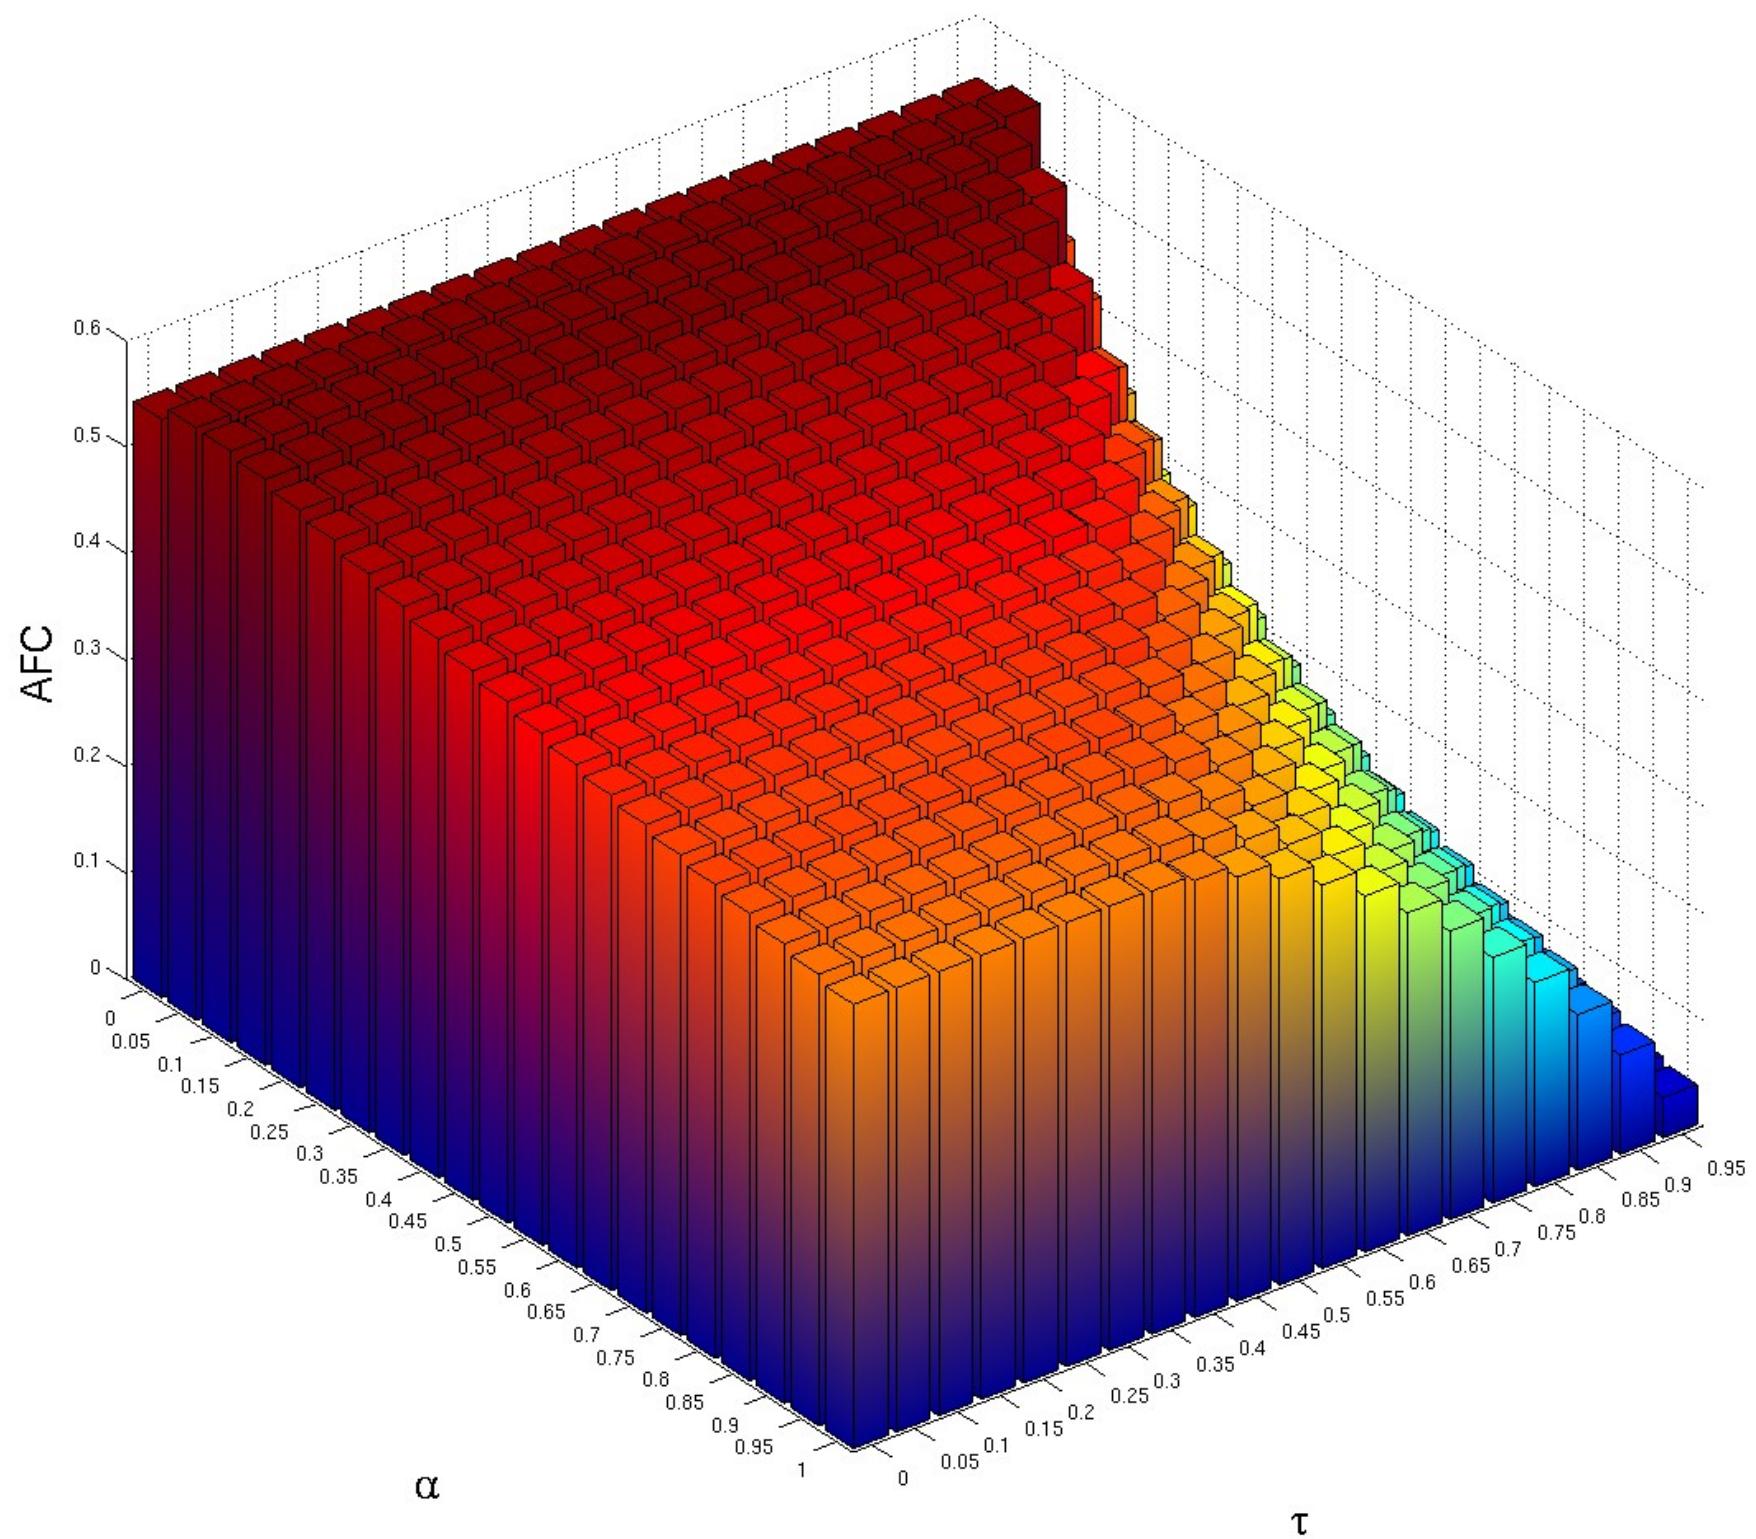

- Weizmann Horse Dataset
 - 328 images in total
 - Training: 30 images
 - Test: 298 images
- I generated a fragment bank for once using the criteria I explained before.
 - 300 fragments in total
- I didn't evaluate the BUS, because it doesn't end up with a figure-ground segmentation.
- I used BUS to generate 9 segmentations per test image. As we go from the 1st level to the 9th level, the number of segments decreases.

How to evaluate?

- I used two measures as the authors did in their paper:
 - Figure consistency
$$|F \cap S| / |F \cup S|$$
 - Overall consistency
 - {Total number of correctly classified foreground and background pixels} / {Total number of pixels}

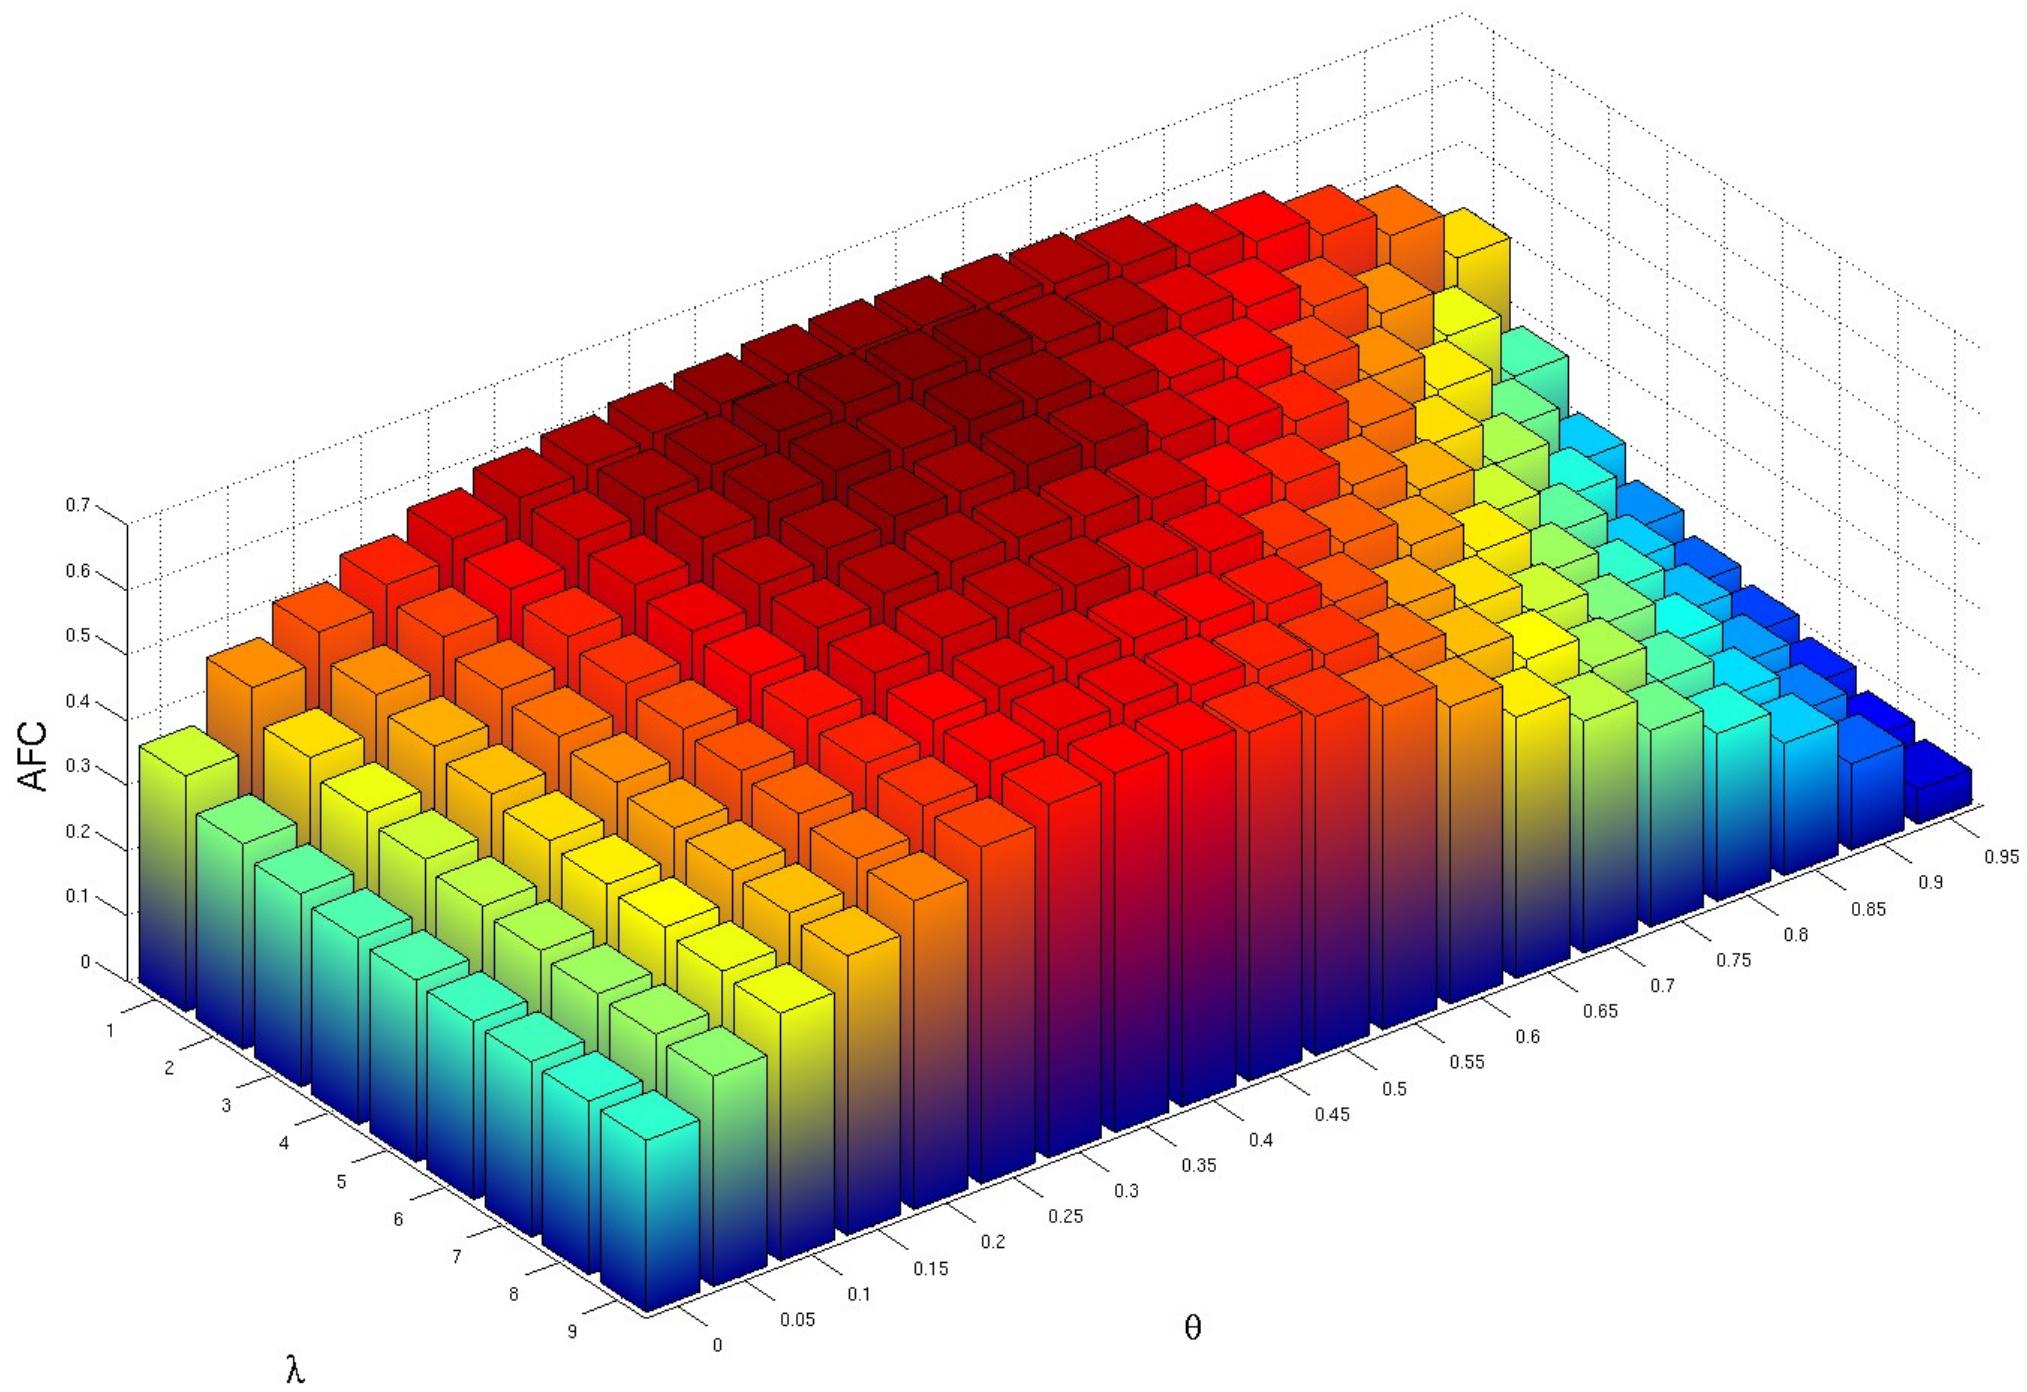

Experimental Results

- Top-down Segmentation
 - There are two parameters:
 - α : Weight representing the contributions of normalized cross correlation response and the spatial consistency of a fragment.
 - τ : Normalized cross correlation response threshold
 - Conducted experiments:
 - $\alpha \in \{0, 0.05, 0.10 \dots 0.95, 1.00\}$
 - $\tau \in \{0, 0.05, 0.10 \dots 0.95\}$
 - According to the average figure consistency
 - Best $\rightarrow \alpha = 0.05, \tau = 0.95, AFC = 55.68\%$
 - Worst $\rightarrow \alpha = 1.00, \tau = 0.95, AFC = 3.79\%$
 - According to the overall consistency
 - Best $\rightarrow \alpha = 0.15, \tau = 0.90, OC = 85.62\%$
 - Worst $\rightarrow \alpha = 1.00, \tau = 0.90, OC = 75.51\%$

Experimental Results

- Combined Segmentation (Using TDS with the highest AFC)
 - There are two parameters:
 - λ : BUS level
 - θ : Threshold to label an entire BU segment as foreground
 - Conducted experiments:
 - λ : 1 – 9
 - $\theta \in \{0, 0.05, 0.10 \dots 0.95\}$
 - According to the average figure consistency
 - Best: $\lambda = 2, \theta = 0.45, \text{AFC} = 63.64\%$
 - Worst: $\lambda = 9, \theta = 0.95, \text{AFC} = 5.28\%$
 - According to the overall consistency
 - Best: $\lambda = 2, \theta = 0.55, \text{OC} = 88.79\%$
 - Worst: $\lambda = 9, \theta = 0.05, \text{OC} = 30.41\%$

Experimental Results

- Comparison of my results to the ones in the paper:
 - Paper: TDS (AFC = **58%**, OC = 84%)
 - Mine: TDS (AFC = 55.68%, OC = **85.62%**)
- Paper: Combined with Flat Segmentation (AFC = **65%**, OC = 85%)
- Mine: Combined with Flat Segmentation (AFC = 63.64%, OC = **88.79%**)

Conclusions

- A simpler version of the TDS approach works comparably well as the one presented in the paper.
- Combining the output of the BU and TD processes increases the segmentation accuracy as expected.

Plan

- Apr 21 – Apr 27: Work on improving the TDS stage.
- Apr 28 – May 4 : Work on using the entire segmentation hierarchy instead of using a fixed level in the BUS stage.
- May 5 – May 11: Work on the components which still require improvements.
- May 12 – May 21: Evaluate the system using different datasets.
